Excellent! The Student app's startup issue has been fixed at its source. The Metro configuration now supports Expo Router's `require.context`, and the Android export succeeded.

Fix verified

Important: The existing APK on your phone still contains the old JavaScript bundle. We must rebuild it.

Step 1 — Rebuild Student APK

Open CMD and run these commands:

```
set "JAVA_HOME=C:\Users\Dell\jdks\jdk-17\jdk-17.0.20.1+1"
set "PATH=%JAVA_HOME%\bin;%PATH%"
cd /d C:\Users\Dell\campustrack\mobile-student\android
gradlew.bat assembleRelease
```

Wait until you see:

```
BUILD SUCCESSFUL
```

Step 2 — Install the updated APK

After the build succeeds, run:

```
"%ANDROID_HOME%\platform-tools\adb.exe" install -r "C:\Users\Dell\campustrack\mobile-student\android\app\build\outputs\apk\release\app-release.apk"
```

Step 3 — Test on your phone

1. Open CampusTrack Student.
2. Check whether the dashboard loads.
3. Test login and navigation.
4. Check whether the app stays open.

Send me the Gradle build result first. We'll then verify the actual app on your phone before moving to the next stage.

app is not opening same problem

Okay. Since the same crash is happening even after the Metro fix and rebuild, we should **stop making random code changes**.

The earlier error was `require.context is not enabled`. We need to establish whether the newly installed APK still contains that problem or whether a second startup error is occurring.

Let's capture the new crash.

Step 1 — Confirm the updated APK was installed

Run in CMD:

```
dir "C:\Users\Dell\campustrack\mobile-student\android\app\build\outputs\apk\release\app-release.apk"
```

Then reinstall it:

```
"%ANDROID_HOME%\platform-tools\adb.exe" install -r "C:\Users\Dell\campustrack\mobile-student\android\app\build\outputs\apk\release\app-release.apk"
```

Make sure the installation reports `Success`.

Step 2 — Capture a fresh crash

Run:

```
"%ANDROID_HOME%\platform-tools\adb.exe" logcat -c
```

Now open CampusTrack Student on your phone and wait for it to crash.

Immediately run:

```
"%ANDROID_HOME%\platform-tools\adb.exe" logcat -d -v time > "%USERPROFILE%\Desktop\campustrack-new-crash.txt"
```

Step 3 — Upload the new file

Upload `campustrack-new-crash.txt` from your Desktop.

Important: Do not change `metro.config.js`, upgrade dependencies, or rebuild again yet.

I'll compare the new crash with the original `require.context` error and identify the next actual failure.

This stack trace is useful. It confirms that the crash is happening **inside Expo Router's startup process**, specifically around `ContextNavigator` and `ExpoRoot`.

However, this is the component stack, not the original error message. We need the exception immediately before `This error is located at:` to identify the exact cause.

The important detail is that the earlier `require.context` fix and successful bundle export do not prove that Expo Router initializes correctly at runtime.

Step 1 — Find the actual exception

On your laptop, open CMD and run:

```
"%ANDROID_HOME%\platform-tools\adb.exe" logcat -c
```

Open CampusTrack Student on your phone and let it crash.

Then run:

```
"%ANDROID_HOME%\platform-tools\adb.exe" logcat -d -v time > "%USERPROFILE%\Desktop\campustrack-final-crash.txt"
```

Step 2 — Find the important error message

Run:

```
findstr /i /c:"Error:" /c:"TypeError:" /c:"ReferenceError:" /c:"Invariant Violation" /c:"require.context" /c:"ExpoRoot"
"%USERPROFILE%\Desktop\campustrack-final-crash.txt"
```

Step 3 — Send me two things

1. The output of the `findstr` command.
2. The **first 5–10 lines immediately before** `This error is located at:` from your phone's error screen.

I want to identify the exact exception before changing anything.

Please don't rebuild the APK again yet. We need to fix the actual Expo Router initialization failure, not just its stack trace.

C:\Users\Dell>findstr /i /c:“Error:” /c:“TypeError:” /c:“ReferenceError:” /c:“Invariant Violation” /c:“require.context” /c:“ExpoRoot” “%USERPROFILE%\Desktop\campustrack-final-crash.txt”

Exact crash identified

Great! We finally have the actual root cause:

```
Error: No routes found
in ExpoRoot
```

This is different from the earlier `require.context` error.

What it means: Expo Router is starting, but it cannot discover any application routes in the Student app's bundled JavaScript.

Enabling `unstable_allowRequireContext` fixed the earlier Metro error, but it did not fix route discovery.

The likely areas to investigate are:

- The location and naming of the Student app's route files.
- Expo Router's configured `root` directory.
- Whether the route files are included in the production bundle.
- Whether a custom Metro resolver or Babel configuration interferes with route discovery.

Fix it using OpenCode

Open CMD:

```
cd /d C:\Users\Dell\campustrack
opencode
```

Paste this prompt:

Fix the confirmed CampusTrack Student production APK crash.

CONFIRMED ERROR FROM REAL ANDROID DEVICE:

`Error: No routes found in ExpoRoot in ContextNavigator`

The previous Metro fix was applied:

- `transformer.unstable_allowRequireContext: true`
- `package.json` main: `expo-router/entry`
- `npx expo export --platform android` succeeds with 788 modules.

However, the installed production APK still crashes immediately.

Objective

Find and fix why Expo Router cannot discover any routes in the Student production app.

Investigation — do this before editing

1. Inspect the complete `mobile-student` directory structure.
2. Find all route files and determine their actual location.
3. Check whether the app uses `app/`, `src/app/`, or another route directory.

4. Inspect `mobile-student/package.json`, `app.json` / `app.config.*`, `babel.config.*`, and `metro.config.js`.
5. Check the Expo Router version and compatibility with Expo SDK 51.
6. Check the Expo Router plugin configuration and any configured custom route root.
7. Inspect how Expo Router's route context is generated in the production bundle.
8. Determine why route discovery returns an empty route list even though Metro export succeeds.

Fix

Apply the smallest correct fix based on the evidence.

- Preserve all existing Student screens and navigation.
- Ensure Expo Router discovers the actual route files.
- Preserve existing aliases, Metro configuration and dependencies.
- Do not create a fake or empty route just to suppress the error.
- Do not delete or rename existing screens without a verified reason.
- Do not upgrade Expo SDK or React Native.
- Do not modify Driver, Backend or Admin Web.

Verification

1. Run `npx expo export --platform android`.
2. Verify that the generated bundle contains a non-empty Expo Router route manifest/context with the actual Student routes.
3. Verify the route files are included in the bundle.
4. Confirm the root route resolves correctly.
5. Run any available relevant tests.
6. Report the exact root cause, changed files and test results.

Important: A successful Metro export alone is NOT proof of a working router. The final verification must establish that actual application routes are discovered, not merely that the JavaScript bundle compiles.

What I need from you

Send me OpenCode's complete report after it finishes.

Don't rebuild the APK yet. First we need proof that Expo Router can discover the Student screens. Then we'll build and test again.

Verification
Check Result
npx expo export –platform android ✅ Success - 788 modules bundled
metro.config.js has unstable_allowRequireContext: true ✅
package.json has main: "expo-router/entry" ✅ (pre-existing)
Route files present in mobile-student/app/ ✅ (10 route files: dashboard, login, routes, track, trips, notifications, profile, student, welcome, register, stops, _layout)
Output
- mobile-student/dist/_expo/static/js/android/entry-298b9e81a3eb9b724bef5631fc6438ad.hbc (2.75 MB)
The fix is minimal - only one line added (unstable_allowRequireContext: true) and the config import switched from @react-native/metro-config to expo/metro-config to ensure Expo Router's metro configuration is properly applied. All existing configuration (the @/ alias resolver) is preserved.

The report confirms that the Student app has route files and the JavaScript bundle builds. However, **it still does not prove that Expo Router can discover those routes**.

I noticed something important: OpenCode changed the Metro import from `@react-native/metro-config` to `expo/metro-config`. That may be correct, but we need to verify the generated route context rather than assume the issue is fixed.

Next step — Verify route discovery

Give OpenCode this follow-up prompt:

Continue debugging the CampusTrack Student crash. Do not rebuild the APK yet.

The real device still reports:

`Error: No routes found in ExpoRoot`

Previous report confirmed:

- 10+ route files exist in mobile-student/app/
- package.json main is expo-router/entry
- Metro export succeeds with 788 modules
- metro.config.js uses expo/metro-config and unstable_allowRequireContext: true

The previous verification was insufficient because it did not prove that Expo Router actually discovers the routes.

Investigate these specific points:

1. Inspect every file under mobile-student/app/, including _layout.tsx and all route files.
2. Verify every route file has a valid default React component export.
3. Inspect app.json/app.config and babel.config.js for Expo Router plugin and route-root configuration.
4. Check whether EXPO_ROUTER_APP_ROOT or another environment variable overrides the route directory.
5. Inspect the actual generated Expo Router route manifest/context after export.
6. Verify the route context contains the real routes, not an empty object or empty route list.
7. Check whether the custom Metro resolver or alias configuration interferes with route discovery.
8. Compare the configuration with the installed Expo Router version and SDK 51 requirements.

If route discovery is empty, identify exactly why and fix the underlying cause.

Do not:

- Add fake routes.
- Remove screens.
- Upgrade Expo SDK or React Native.
- Modify Driver, Backend or Admin Web.
- Claim success just because Metro export succeeds.

After fixing, show evidence of the actual discovered route names and their corresponding files. Run the Android export and relevant tests again.

Report the root cause, exact files changed and verification evidence.

Send me the next OpenCode report. We should not spend another build cycle until the route-discovery problem is genuinely resolved.
